Outline

- Why program synthesis
- 2 What is program synthesis
- 3 How program synthesis works
- 4 Conclusions and future work

Why program synthesis

- Why program synthesis
- 2 What is program synthesis
- 3 How program synthesis works
- 4 Conclusions and future work

Why program synthesis

Programmers

- General purpose programming assistance
 - Automatically discover tricky/menial details
 - Automated debugging (Identified suspected region and a description of desired behaviors)
- Discovery of new algorithms

Why program synthesis

End-users

- Develop utility programs with no programming background
- Teaching
 - Automated problem solving

What is program synthesis

- Why program synthesis
- What is program synthesis
- 3 How program synthesis works
- 4 Conclusions and future work

What is program synthesis

Synthesize an **executable program** from user intent expressed in form of some **constraints**

What is program synthesis

Find a program P that meets a spec ϕ (input,output):

$$\exists P \ \forall x \ . \ \phi(x, P(x))$$

When to use synthesis:

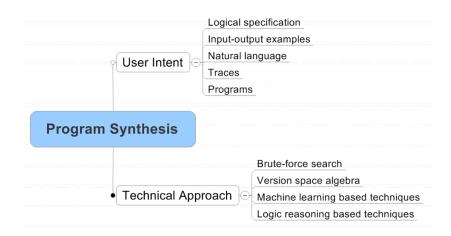

productivity: when writing ϕ is faster than writing P

correctness: when proving ϕ is easier than proving P

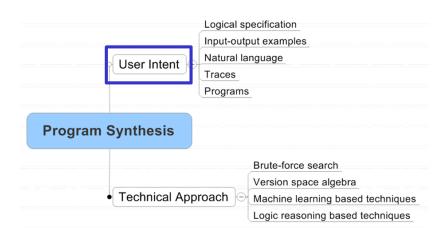

How program synthesis works

- Why program synthesis
- 2 What is program synthesis
- 3 How program synthesis works
- 4 Conclusions and future work

How program synthesis works

User intent

Logical specification

Logical relation between inputs and outputs of a program

Example: sorting algorithm

$$\forall k. \ (0 \le k < n-1) \Longrightarrow (B[k] \le B[k+1]) \tag{1}$$

$$\land \quad \forall k \; \exists j. \; (0 \le k < n) \Longrightarrow (0 \le j < n \land B[j] = A[k]) \; (2)$$

Logical specification

- Require additional knowledge of logic
- Harder to get it **right**
- Not be preferred by end-users

Natural language

Map natural language sentences into logical representations

Input-output examples

User driven interaction

- User **inspects**
- User add new input-output example

Synthesizer driven interaction

Synthesizer finds distinguishing input

Input-output examples

Example: Bitvector program

- Masks off the rightmost contiguous sequence of 1s in the input bitvector
- Synthesizer driven interaction

User	Oracle		
Input → Output	Program 1	Program 2	Distinguishing Input ?
$01011 \to 01000$	(x+1) & (x-1)	(x+1) & x	00000?
$00000 \to 00000$	$-(\neg x) \& x$	$(((x\& - x) \mid -(x-1))\&x) \oplus x$	00101 ?
$00101 \to 00100$	(x+1)&x		01111 ?
$01111 \to 00000$		•••	00110 ?
$00110 \to 00000$			01100 ?
$01100 \to 00000$			01010 ?
$01010 \rightarrow 01000$	(((x-1) x)+1)&x	None	Program is
			(((x-1) x)+1)&x

Traces

A **trace** is a detailed **step-by-step** description of how the program should behave on a **given input**

Example: Compute factorial(n)

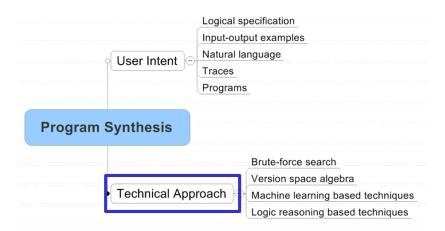

- A demonstration for input 7
- The string $7 \times 6 \times 5 \times 4 \times 3 \times 2$ or the recursive trace $7 \times factorial(6)$
- Easier to describe than providing the final simplified output
 5040

Programs

Partial programs

- Sketch interger holes
- Some tricky or mundane details in the programs

Technical approach

Existing programs

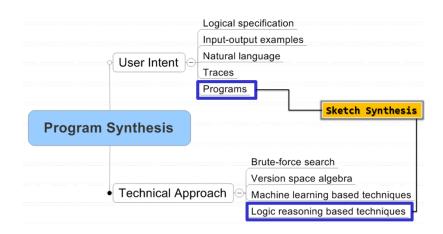

Sketch Synthesis

- PLDI 07'
- Armando Solar-Lezama MIT

String transformation

- POPL 12'
- Sumit Gulwani MSR

Sketch synthesis

Sketch synthesis

- **Specification** of the desired **functionality**, usually to be *unoptimized and inefficient* but *easy* to implement
- Partial implementation sketch of an optimized program
- Synthesizer completes the sketch to behave like the specification

Sketch synthesis

Demo

Logic reasoning technique

Sketch compiler

- Generalized **boolean satisfiability** problem
- Replace with *Control variables*
- Translate to boolean functions

Sketch resolution problem

1. 2QBF function

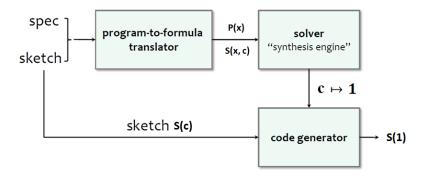

$$\exists c. \forall x. P(x) = S(x, c)$$

2. Counterexample-driven search procedure

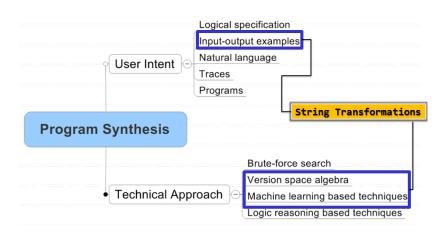

$$\exists c. \forall x \in E. P(x) = S(x, c)$$

3. SAT solver

Sketching resolver

String transformation

String transformation

Synthesizing a wide range of **string processing programs** in spreadsheets from **input-output examples**

String transformation

Example: Extracting directory name

Input v_1	Output
$Company \setminus Code \setminus index.html$	$Company \setminus Code \setminus$
$Company \setminus Docs \setminus Spec \setminus specs.doc$	$Company \setminus Docs \setminus Spec \setminus$

Example: Generate abbreviation

Input v_1	Output
International Business Machines	IBM
Principles Of Programming Languages	POPL
International Conference on Software Engineering	ICSE

Language of string programs

More expressive language to reduce search complexity

- More expressive language
 (eg: concatenate, switch, substring, etc)
- Tradeoff between the expressiveness of a language and the complexity of the search technique

Language of string programs

Example: Extracting directory name

Input v_1	Output
Company\Code\index.html	$Company \setminus Code \setminus$
$Company \setminus Docs \setminus Spec \setminus specs.doc$	$Company \setminus Docs \setminus Spec \setminus$

String Program:

$$\overline{\mathit{SubStr}(v_1,\mathit{CPo}}s(0),\mathit{Pos}(\mathit{SlashTok},\epsilon,-1))$$

Ranking strategies

- **Shorter** programs eg: fewer conditions, shorter string expressions
- Less number of constants

Limitations and follow-up work

This program: syntactic manipulations of strings

- Semantic manipulations
- Manipulations of tables

Future work

- Why program synthesis
- 2 What is program synthesis
- 3 How program synthesis works
- 4 Conclusions and future work

Conclusions

- Revolution in computing
- How to what

Future work

- Combine various forms of user intent in a unified programming interface
- Combine the power of various search techniques

Q & A

Thank you!
